Figure 2: Different k values with their distortions

## Results

In this experiment we use k-mean algorithm for clustering the sentences that already clustered by humans. To determine the ideal k value ,i.e. number of clusters, we test clustering algorithm with different k values then plot them with their distortion values that calculated with distortion function. When k value increases, the centroids are closer to the clusters centroids. At some point, the improvements will drop rapidly, forming the shape of the elbow and that point is the optimal value for k and this value is 3-4 which is very similar to real number of classes which are müspet,menfi and uyarı.
